

# Fast Computation of Multivariate Subresultants

Yunus GÜRLEK, Frederic XIA

Supervisor: Weijia WANG

May 22, 2026

# Outline

- 1 Introduction
- 2 State of the Art and Contribution
- 3 Proposed Algorithm
- 4 Benchmarks
- 5 Conclusion

## Problem

Given  $f, g \in R[x]$  with  $\deg(f) = p > q = \deg(g)$ , compute

$$\gcd(f, g), \quad \text{Res}(f, g), \quad (\text{sResP}_i(f, g))_{0 \leq i \leq q}.$$

# Introduction

## Problem

Given  $f, g \in R[x]$  with  $\deg(f) = p > q = \deg(g)$ , compute

$$\gcd(f, g), \quad \text{Res}(f, g), \quad (\text{sResP}_i(f, g))_{0 \leq i \leq q}.$$

## Main idea

Use subresultants and specialization to replace expensive symbolic computations by many cheaper univariate computations.

# Introduction

## Problem

Given  $f, g \in R[x]$  with  $\deg(f) = p > q = \deg(g)$ , compute

$$\gcd(f, g), \quad \text{Res}(f, g), \quad (\text{sResP}_i(f, g))_{0 \leq i \leq q}.$$

## Main idea

Use subresultants and specialization to replace expensive symbolic computations by many cheaper univariate computations.

## Background

Univariate and multivariate polynomials, GCD, resultants, subresultants and subresultant polynomials.

# Euclidean Algorithm: Correct but Costly

Euclidean GCD:

$$r_0 = f, \quad r_1 = g, \quad r_{i+1} = r_{i-1} \bmod r_i.$$

# Euclidean Algorithm: Correct but Costly

Euclidean GCD:

$$r_0 = f, \quad r_1 = g, \quad r_{i+1} = r_{i-1} \bmod r_i.$$

## Issue

Over rings such as  $\mathbb{Z}$ , coefficient sizes may grow quickly during division.

# Euclidean Algorithm: Correct but Costly

Euclidean GCD:

$$r_0 = f, \quad r_1 = g, \quad r_{i+1} = r_{i-1} \bmod r_i.$$

## Issue

Over rings such as  $\mathbb{Z}$ , coefficient sizes may grow quickly during division.

$$f = x^8 + x^6 - 3x^4 - 3x^3 + 8x^2 + 2x - 5,$$

$$g = 3x^6 + 5x^4 - 4x^2 - 9x + 21.$$

$$r_2 = -\frac{5}{9}x^4 + \frac{1}{9}x^2 - \frac{1}{3}, \quad r_3 = -\frac{117}{25}x^2 - 9x + \frac{441}{25},$$

$$r_4 = \frac{233150}{19773}x - \frac{102500}{6591}, \quad r_5 = -\frac{1288744821}{543589225}.$$

$$\gcd(f, g) = 1.$$

# Euclidean Algorithm: Correct but Costly

Euclidean GCD:

$$r_0 = f, \quad r_1 = g, \quad r_{i+1} = r_{i-1} \bmod r_i.$$

## Issue

Over rings such as  $\mathbb{Z}$ , coefficient sizes may grow quickly during division.

$$f = x^8 + x^6 - 3x^4 - 3x^3 + 8x^2 + 2x - 5,$$

$$g = 3x^6 + 5x^4 - 4x^2 - 9x + 21.$$

$$r_2 = -\frac{5}{9}x^4 + \frac{1}{9}x^2 - \frac{1}{3}, \quad r_3 = -\frac{117}{25}x^2 - 9x + \frac{441}{25},$$

$$r_4 = \frac{233150}{19773}x - \frac{102500}{6591}, \quad r_5 = -\frac{1288744821}{543589225}.$$

$$\gcd(f, g) = 1.$$

Using Subresultants:

## Key property

The subresultant subsequence of polynomials is proportional to the Euclidean remainder sequence, and GCD is the final non-zero subresultant polynomial.

# Euclidean Algorithm: Correct but Costly

Euclidean GCD:

$$r_0 = f, \quad r_1 = g, \quad r_{i+1} = r_{i-1} \bmod r_i.$$

## Issue

Over rings such as  $\mathbb{Z}$ , coefficient sizes may grow quickly during division.

$$f = x^8 + x^6 - 3x^4 - 3x^3 + 8x^2 + 2x - 5,$$

$$g = 3x^6 + 5x^4 - 4x^2 - 9x + 21.$$

$$r_2 = -\frac{5}{9}x^4 + \frac{1}{9}x^2 - \frac{1}{3}, \quad r_3 = -\frac{117}{25}x^2 - 9x + \frac{441}{25},$$

$$r_4 = \frac{233150}{19773}x - \frac{102500}{6591}, \quad r_5 = -\frac{1288744821}{543589225}.$$

$$\gcd(f, g) = 1.$$

Using Subresultants:

## Key property

The subresultant subsequence of polynomials is proportional to the Euclidean remainder sequence, and GCD is the final non-zero subresultant polynomial.

For the same  $f$  and  $g$ :

$$\text{sResP}_5(f, g) = 15x^4 - 3x^2 + 9,$$

$$\text{sResP}_3(f, g) = 65x^2 + 125x - 245,$$

$$\text{sResP}_2(f, g) = 9326x - 12300,$$

$$\text{sResP}_0(f, g) = 260708.$$

$$\gcd(f, g) = 1.$$

# State of the Art and Contribution

State of the art:

- 1750, Subresultants were already known to Euler.

# State of the Art and Contribution

State of the art:

- 1750, Subresultants were already known to Euler.
- 1967, Collins used them heavily in computational algebra.

# State of the Art and Contribution

State of the art:

## This work

Design and implement (on FLINT) a fast algorithm for subresultants over  $\mathbb{Q}$ ,  $\mathbb{Z}$ , and  $\mathbb{F}_p$ .

## Technique

Use evaluation and interpolation, generalizing Collins's resultant algorithm.

## Observed performance

Speedups up to  $7\times$  on benchmarks with total degree of bitsize 6 and coefficient bit size 50, both on FMPZ and FMPQ.

# Subresultant Polynomials

For  $0 \leq i \leq q$  and  $0 \leq j \leq i$ , let  $M_{i,j}(f, g)$  be the corresponding Sylvester-Habicht minor.

## Definition

$$\text{sResP}_i(f, g) = \sum_{j=0}^i \det(M_{i,j}(f, g)) x^j.$$

## Non-defective case

$$\deg(\text{sResP}_i(f, g)) = i.$$

# Subresultant Polynomials

For  $0 \leq i \leq q$  and  $0 \leq j \leq i$ , let  $M_{i,j}(f, g)$  be the corresponding Sylvester-Habicht minor.

## Definition

$$\text{sResP}_i(f, g) = \sum_{j=0}^i \det(M_{i,j}(f, g)) x^j.$$

## Non-defective case

$$\deg(\text{sResP}_i(f, g)) = i.$$

- Non-zero subresultants encode Euclidean remainders.
- Defective subresultants reveal degree drops.
- Zero subresultants indicate gaps in the sequence.
- Last non-zero subresultant polynomial equals the GCD.

## Consequence

The GCD and resultant can be computed without division in the fraction field.

# Multivariate Setting

Let

$$f, g \in \mathbb{Z}[x_1, \dots, x_n].$$

View them as univariate polynomials in  $x_1$ :

$$f, g \in R[x_1], \quad R = \mathbb{Z}[x_2, \dots, x_n].$$

Goal

Compute

$$\text{Res}_{x_1}(f, g), \quad \text{sResP}_i(f, g).$$

# Multivariate Setting

Let

$$f, g \in \mathbb{Z}[x_1, \dots, x_n].$$

View them as univariate polynomials in  $x_1$ :

$$f, g \in R[x_1], \quad R = \mathbb{Z}[x_2, \dots, x_n].$$

Goal

Compute

$$\text{Res}_{x_1}(f, g), \quad \text{sResP}_i(f, g).$$

Symbolic computation over

$$R = \mathbb{Z}[x_2, \dots, x_n]$$

can be expensive.

Instead, choose evaluation points

$$\eta \in \mathbb{Z}^{n-1}$$

and compute in

$$\mathbb{Z}[x_1].$$

# Backbone of the Approach

## Specialization of the Resultant

Let

$$h = \text{lc}_{x_1}(f) \text{lc}_{x_1}(g).$$

### Valid evaluation point

If  $h(\eta) \neq 0$ , then

$$\text{Res}_{x_1}(f(\eta), g(\eta)) = \text{Res}_{x_1}(f, g)(\eta).$$

# Backbone of the Approach

## Specialization of the Resultant

Let

$$h = \text{lc}_{x_1}(f) \text{lc}_{x_1}(g).$$

### Valid evaluation point

If  $h(\eta) \neq 0$ , then

$$\text{Res}_{x_1}(f(\eta), g(\eta)) = \text{Res}_{x_1}(f, g)(\eta).$$

### Bad points

Degree drops after evaluation can break the equality.

# Backbone of the Approach

## Specialization of the Resultant

Let

$$h = \text{lc}_{x_1}(f) \text{lc}_{x_1}(g).$$

### Valid evaluation point

If  $h(\eta) \neq 0$ , then

$$\text{Res}_{x_1}(f(\eta), g(\eta)) = \text{Res}_{x_1}(f, g)(\eta).$$

### Bad points

Degree drops after evaluation can break the equality.

## Degree Bound

Let

$$D = \deg_{x_1}(f) \deg_{x_2, \dots, x_n}(g) + \deg_{x_1}(g) \deg_{x_2, \dots, x_n}(f).$$

# Backbone of the Approach

## Specialization of the Resultant

Let

$$h = \text{lc}_{x_1}(f) \text{lc}_{x_1}(g).$$

### Valid evaluation point

If  $h(\eta) \neq 0$ , then

$$\text{Res}_{x_1}(f(\eta), g(\eta)) = \text{Res}_{x_1}(f, g)(\eta).$$

### Bad points

Degree drops after evaluation can break the equality.

## Degree Bound

Let

$$D = \deg_{x_1}(f) \deg_{x_2, \dots, x_n}(g) + \deg_{x_1}(g) \deg_{x_2, \dots, x_n}(f).$$

### Bound

$$\deg(\text{Res}_{x_1}(f, g)) \leq D.$$

# Backbone of the Approach

## Specialization of the Resultant

Let

$$h = \text{lc}_{x_1}(f) \text{lc}_{x_1}(g).$$

### Valid evaluation point

If  $h(\eta) \neq 0$ , then

$$\text{Res}_{x_1}(f(\eta), g(\eta)) = \text{Res}_{x_1}(f, g)(\eta).$$

### Bad points

Degree drops after evaluation can break the equality.

## Degree Bound

Let

$$D = \deg_{x_1}(f) \deg_{x_2, \dots, x_n}(g) + \deg_{x_1}(g) \deg_{x_2, \dots, x_n}(f).$$

### Bound

$$\deg(\text{Res}_{x_1}(f, g)) \leq D.$$

### Interpolation cost

For  $n = 2$ , at most  $D + 1$  evaluation points are needed.

# Proposed Bivariate Resultant Algorithm

For  $f, g \in \mathbb{Z}[x_1, x_2]$ :

$$N = \deg_{x_1}(f) \deg_{x_2}(g) + \deg_{x_1}(g) \deg_{x_2}(f).$$

- 1 Choose  $N + 1$  good evaluation points.
- 2 Compute

$$y_i = \text{Res}(f(x_i), g(x_i)).$$

- 3 Interpolate

$$R = \text{interpolate}(x_i, y_i, N + 1).$$

# Proposed Bivariate Resultant Algorithm

For  $f, g \in \mathbb{Z}[x_1, x_2]$ :

$$N = \deg_{x_1}(f) \deg_{x_2}(g) + \deg_{x_1}(g) \deg_{x_2}(f).$$

- 1 Choose  $N + 1$  good evaluation points.
- 2 Compute

$$y_i = \text{Res}(f(x_i), g(x_i)).$$

- 3 Interpolate

$$R = \text{interpolate}(x_i, y_i, N + 1).$$

Implemented strategies:

- Random Points
- Random Positive Points
- Small Random Points
- Small Random Positive Points
- Ordered Points
- Ordered Positive Points

Small and ordered points usually reduce interpolation cost.

## Benchmark Setup

- Apple MacBook, 8-core Apple M2 SoC
- 16 GB unified memory
- Average of 5 independent trials
- Coefficient bit size fixed at 50
- Comparison against FLINT bivariate resultant computation

# FMPZ Benchmarks

## Bitsize 3

Random interpolation points with large bitsize are much slower.

Not too much difference between other benchmarks.

Length of the polynomial does not affect the performance significantly.

# FMPZ Benchmarks

## Bitsize 4

Library implementation is slower than our algorithm.

Not too much difference between random interpolation with small bitsize and ordered points.

Execution time increases as the length of the polynomial increases.

# FMPZ Benchmarks

## Bitsize 5

Point bitsize strongly affects interpolation time.

We observe high fluctuations in the performance because of random polynomial generation.

Not an accurate measurement of dependance to the length, but the ratio between different methods.

# FMPZ Benchmarks

fmpz - Execution Time vs Length of the Polynomial for Exponent Bitsize 6

## Bitsize 6

We remove random interpolation methods.

We observe 6x performance difference between our methods.

Difference becomes more important as the length of the polynomial & bitsize of the exponent increase.

## Benchmark Setup

- Apple MacBook, 8-core Apple M2 SoC
- 16 GB unified memory
- Average of 5 independent trials
- Coefficient bit size fixed at 50
- Comparison against FLINT bivariate resultant computation

# FMPQ Benchmarks

## Bitsize 3

Random interpolation points with large bitsize are much slower.

Not too much difference between other benchmarks.

Length of the polynomial does not affect the performance significantly.

# FMPQ Benchmarks

fmpp - Execution Time vs Length of the Polynomial for Exponent Bitsize 4

## Bitsize 4

Library implementation is slower than our algorithm.

Not too much difference between random interpolation with small bitsize and ordered points.

Execution time increases as the length of the polynomial increases.

# FMPQ Benchmarks

fmpq - Execution Time vs Length of the Polynomial for Exponent Bitsize 5

## Bitsize 5

Point bitsize strongly affects interpolation time.

We observe high fluctuations in the performance because of random polynomial generation.

Not an accurate measurement of dependance to the length, but the ratio between different methods.

# FMPQ Benchmarks

## Bitsize 6

We remove random interpolation methods.

We observe 7x performance difference between our methods.

Behaviour is similar to  $\mathbb{Z}$  mostly.

# Wolfram Benchmark

## Bitsize 6

We only compare our fastest implementation against Wolfram.

We observe Wolfram performs better than FLINT.

Yet, our implementation is still faster by 2.5x speedup.

## Summary of Results

- Subresultants control coefficient growth in GCD/resultant computations.
- Specialization is valid away from leading-coefficient zeros.
- Interpolation recovers multivariate resultants and subresultants.
- Evaluation point choice is critical for performance.
- Ordered or small-bit-size points work best in the benchmarks.
- Our implementation improves FLINT's performance, especially for polynomials with high degree and length.

## Summary of Results

- Subresultants control coefficient growth in GCD/resultant computations.
- Specialization is valid away from leading-coefficient zeros.
- Interpolation recovers multivariate resultants and subresultants.
- Evaluation point choice is critical for performance.
- Ordered or small-bit-size points work best in the benchmarks.
- Our implementation improves FLINT's performance, especially for polynomials with high degree and length.

## Next Steps

- Benchmark subresultant implementation for bivariate polynomials.
- Extend implementation from resultants / subresultants to subresultant polynomials.
- Extend implementation to higher dimension multivariate polynomials (note that number of points for interpolation increases -  $(D + 1)^{n-1}$ ).
- Optimize, test, and benchmark for higher degree and length polynomials.
